CHAPTER 1 Introduction

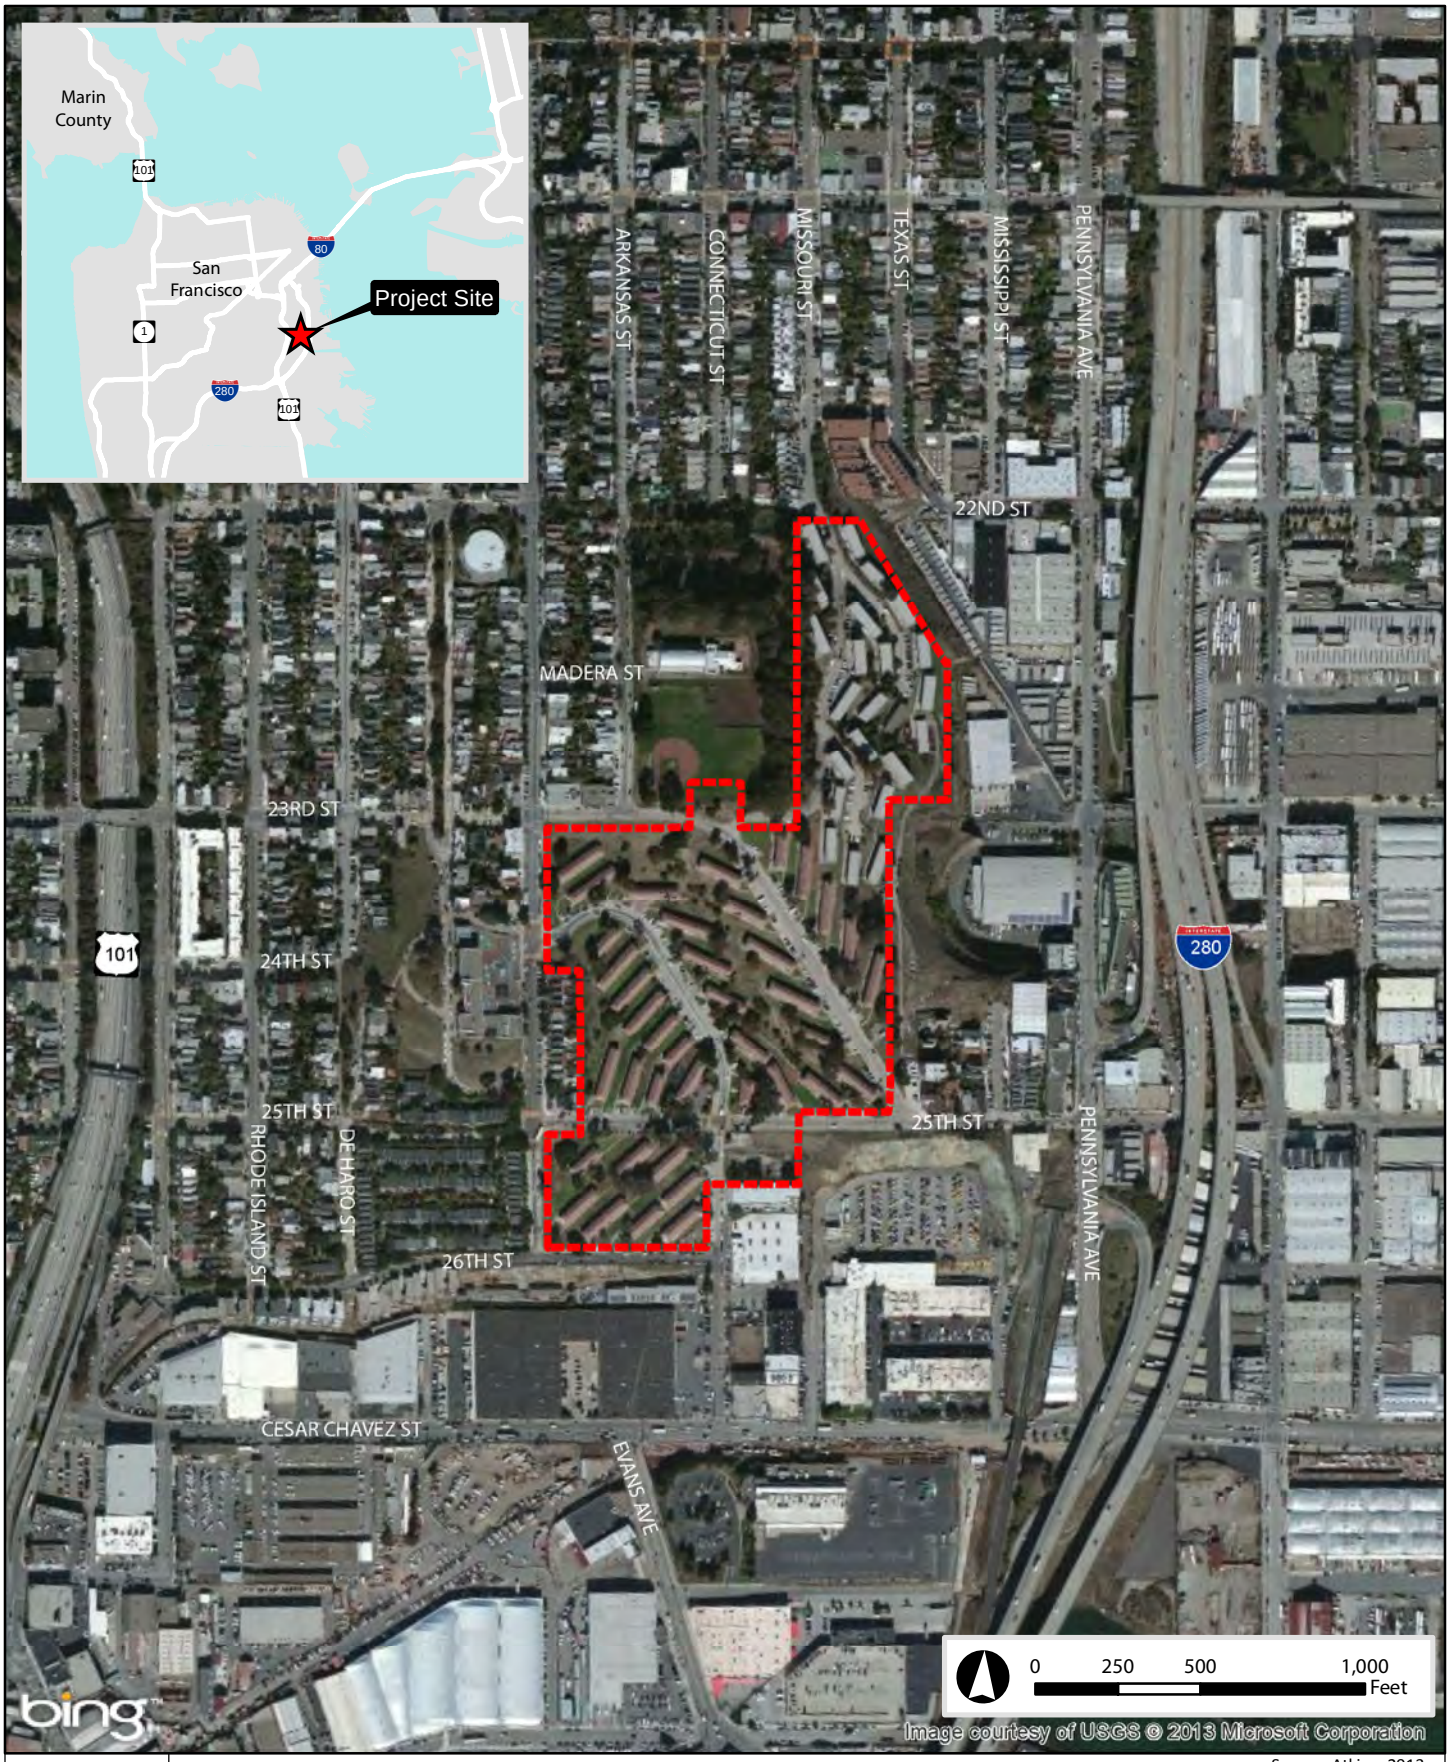
This air quality technical report assesses the potential for air quality impacts to occur as a result of the Potrero HOPE SF Master Plan Project, herein referred to as the "Project." The Project consists of the redevelopment of the Potrero Terrace and Annex (Potrero) housing developments as a part of a program to revitalize distressed public housing developments in San Francisco. The Project would replace all existing housing units at the site; incorporate additional affordable housing and market-rate homes into the community; and add amenities such as open space, retail opportunities, and neighborhood services. The Project would include new vehicle connections, new pedestrian connections, a new circulation concept, and new transit stops. In addition, the Project would incorporate green construction and sustainable principles.

Implementation of the proposed Project would result in criteria air pollutant and toxic air contaminant (TAC) emissions from the construction and operation of the re-developed land uses. Specifically operational emissions would result from the day-to-day operation of the residential and non-residential land uses, the operation of a diesel backup generator, and vehicle trips. Operational TAC emissions would result from two primary sources: (1) a proposed diesel backup emergency generator, and (2) vehicle trips. Construction activities emit fugitive dust, criteria air pollutants, and TACs, most notably diesel particulate matter. This report is intended to satisfy the City of San Francisco's requirement for an air quality impact analysis by examining the impacts of the Project and identifying measures to reduce emissions and resulting impacts, where applicable.

1.1 PROJECT BACKGROUND

The approximately 39-acre site (including existing roadways) is located in the Potrero Hill neighborhood of San Francisco, California and is roughly bounded by 22nd Street to the north, Pennsylvania Avenue to the east, 26th Street to the south, and Wisconsin Street to the west, as depicted in Figure 1, Project Location, p. 4.

The HOPE SF Program has identified the need for redevelopment of the Potrero housing developments and has included the Project as a part of its program to revitalize distressed public housing in San Francisco. The Project site is comprised of two of the oldest public housing developments in San Francisco, Potrero Terrace and Potrero Annex, and contains 620 residences that are in various stages of physical decay. Together, these public housing developments accommodate a population of approximately 1,200 people. In addition to distressed and deteriorated housing, the project site contains dead-end streets and steep topography that isolate residents from the surrounding Potrero Hill neighborhood. The Project would replace the deteriorated existing housing units and provide other improvements such as a community center, daycare and preschool facilities, as well as retail establishments.



Source: Atkins, 2013

FIGURE 1

Project Location

100017266

Potrero Hope SF Master Plan

The project site currently consists of 59,200 square feet (sf) of existing residential development. Twenty-three residential buildings, comprising 151 units, are located on the Potrero Annex portion and 38 residential buildings, comprising 469 units, are located on the Potrero Terrace portion. Of the 620 total units, 85 percent were occupied at the time the Notice of Preparation (NOP) was published on November 9, 2009. In addition to the residential occupancy, 12 units are currently occupied by as a 3,500-square-foot daycare/preschool facility located at 71 Turner Terrace. Implementation of the proposed Project would result in the demolition of all existing uses on the project site.

The project site is surrounded by existing development. To the north and west, the project site is predominantly bordered by residential land use with some local serving commercial uses. The Starr King Elementary School is located approximately 60 feet west of the project site directly across Wisconsin Street, and the Potrero Hills Recreation Center is located directly north and west of the project site. Commercial, general industrial, and some residential land uses border the project site to the east. Industrial and commercial land uses are directly south.

In developing the Project, the San Francisco Mayor's Office of Housing (MOH), the San Francisco Housing Authority, and BRIDGE Housing Corporation (Project Sponsor) determined the appropriate mix of public housing, below market-rate, and market-rate housing that would meet the various objectives and goals of the project partners for the proposed Potrero HOPE SF Master Plan. These objectives and goals include satisfying the need to revitalize distressed public housing, creating a suitable variety of economically integrated unit types, and satisfying the Project's financial requirements. It was determined that up to 1,700 residential units, 15,000 sf of retail/flex space, 35,000 sf of community space, and approximately 7 acres of open space would best satisfy these criteria.

1.2 PROJECT DESCRIPTION

The Project would demolish the existing 620 affordable housing units, including the 12 units currently used as a preschool/daycare facility. The site would be redeveloped with up to 1,700 mixed-income housing units (up to 970 affordable, 630 market rate, and 100 senior units), 15,000 sf of retail facilities, a 35,000 sf community center (including daycare and preschool facilities), several small parks and open spaces, and associated residential parking facilities (Figure 2, Proposed Project Land Use, p. 6). A summary of existing and proposed land uses are provided in Table 1, Existing and Proposed Land Uses, p. 7.

The Project would include a back-up emergency generator. The emergency generator is anticipated to be located within the community center property located in the central section of Phase 2. The generator would be located within 15 meters of future residential and preschool/daycare land uses. The Project also anticipates the inclusion of local-serving retail uses. While the exact nature of the new retail uses is unknown, none of these uses are anticipated to include any stationary sources of TACs; therefore, only the proposed generator is a project-related stationary source of TACs.

a. Would be part of the community center.

b. There are 620 total units currently existing on the project site including the 12 units used for preschool and daycare uses.

Implementation of the Project would result in an increase in area traffic by approximately 12,000 daily vehicle trips.[1] Under existing conditions, Potrero Avenue, Cesar Chavez Street, and Pennsylvania Avenue have the greatest levels of traffic at 18,510, 15,610, and 13,180 vehicles per day, respectively. Under 2030 cumulative (build-out) conditions, annual average daily vehicle trips (ADT) for these streets are anticipated to increase to 25,660; 29,910; and 18,110, respectively. At build-out, project-related traffic would account for 670, 3,170, and 520 ADT, respectively, for Potrero Avenue, Cesar Chavez Street, and Pennsylvania Avenue.

Three bus lines currently operate within the Project vicinity. Several new transit stops are proposed within the project site on the reconfigured street system. The Project would relocate/consolidate existing bus stops and create new stops for a total of 12 bus stops within the project vicinity as a result of Project implementation. The relocation/consolidation of bus stops would not substantially affect air pollutant emissions because the project would not result in new bus service trips or substantial changes to bus vehicle miles travelled and thus are not considered further.

1.3 PROJECT PHASING

The Project would be developed in three non-overlapping phases spanning from 2015 to 2025. Phase 1 consists of the vicinity south of 25th Street in the Terrace portion of the project site. Phase 2 consists of the area between 23rd Street and 25th Street, or the remaining portions of the Terrace site. Figure 3, Construction Phasing, p. 8, shows the locations of the three phases of construction. Phase 3 consists of

100017266

Potrero Hope SF Master Plan

development of the entire Annex site. The exact timing of construction of each phase has not been determined. However, Phase 1 would last approximately 26 months with streets closed for approximately eight months, and Phases 2 and 3 would each last 48 months with streets closed for approximately 12 months during each phase. Each phase of construction would include demolition of existing facilities, followed by grading and construction of new facilities. Where possible, the Project would accommodate on-site relocation of existing residents.

Table 2, Land Use Comparison, shows the anticipated land use demolition and new construction proposed during each of these phases. The table shows the residential uses by 1 bedroom, 2+ bedrooms, or senior units as the trip generation rates differ for each of these types of residential uses; therefore, these uses are each distinctly accounted for in the air quality emissions analysis. Further, a portion of the community center would include the daycare and preschool land uses. The space allocated for those uses within the community center is shown separately to coordinate with the air quality emissions modeling.

Table 2 Land Use Comparison

SOURCE: CDM Smith, *Potrero HOPE Transportation Study* (July 11, 2012).

As stated, the exact timing of the construction activities is unknown; however, there are three scenarios that represent the most likely order of development. Construction Scenario A would construct Phase 1 followed by Phase 2 followed by Phase 3. Scenario B would construct Phase 3 followed by Phase 1 followed by Phase 2, and Scenario C would construct Phase 3 followed by Phase 2 followed by Phase 1.

With the existing occupancy of the site at 85 percent, there are residents currently living in each of the three Project Phases who would have to be relocated while that Phase is being re-developed. The intent is to relocate the residents on site; therefore, while one phase is under construction, those residents would be accommodated in one of the other phases. Therefore, on-site residents have the potential to be relocated several times during the Project construction. For example, under Scenario A, an existing resident has the potential to be relocated from Phase 1 to Phase 2 (for construction of Phase 1), then from Phase 2 to Phase 3 (for construction of Phase 2), then from Phase 3 back to Phase 1 or Phase 2 (for construction of Phase 3). There is the potential that a final move would occur after buildout is complete, but it is unlikely unless that resident was to ultimately reside in Phase 3. Based on the construction scenario implemented and the original location of the existing resident, there are many

variations of on-site relocation that could occur. It is anticipated, however, that on-site relocations would be staged such that the residents would have the least amount of moving necessary to remain on site and to accomplish the Project needs.

The daycare center,[2] similar to the residential receptors, would relocate throughout the 10-year construction period as detailed in Section 1.3, Project Phasing, p. 7. However, there are only three potential scenarios to represent the relocation of the daycare on site, which would be determined by the Construction Scenario implemented.

- Under Scenario A the daycare center would be located in the existing building in Phase 3 during the construction of Phase 1 and Phase 2, and then relocated to the new daycare facility in Phase 2 during the construction of Phase 3.
- Under Scenario B, the daycare would be located in Phase 1 then relocated to an unknown location in Phase 3 and remain in that location during the construction of Phases 1 and 2.
- Under Scenario C, the daycare would be located in Phase 1 during the construction of Phases 3 and 2 then would be moved to the new building in Phase 2 during the construction of Phase 1.

During Project construction, the following types of activities (sub-phases) would be expected: abatement and demolition, site preparation and earthwork/grading, new infrastructure construction, and building construction. Some activities could occur simultaneously. Demolition and construction activities would be limited to weekdays and daytime hours (7:00 a.m. to 7:00 p.m.).

Development of the Project would include grading of approximately 248,160 cubic yards (CY) of earthwork over the three phases of construction. Phase 1 would disturb 7.4 acres and 18,000 CY of soil would be used as fill with 7,400 CY exported off site. During Phase 2, 19.45 acres would be disturbed and 135,680 CY would be excavated and filled on site; however, a total 213,490 CY would be necessary for fill and, as such, 77,810 CY of fill would need to be imported. During Phase 3, 12.34 acres would be disturbed and 35,730 CY of soil would be used as fill with 51,350 CY exported off site. Site earthwork and grading would typically be performed using standard construction equipment, such as excavators, loaders, tractors, graders, and water trucks. The timing of each of the construction sub-phases is based on the level of construction activities anticipated under each sub-phase and is shown in Table 3, Project Construction Schedule, p. 11. Due to the size of the phasing areas, it is assumed that the demolition and grading activities may occur on the same day as well as building and coating activities during construction; therefore, the months depicted for each construction sub-phase in Table 3 will not add to the total phase lengths shown.

[2] Note that it is anticipated that children living within the Project boundaries would be the only children attending the daycare. Therefore the maximum risk to these children would be represented by the Resident risk and is not a combination of the resident risk and the daycare risk. The daycare risk is provided to show potential risk in case an individual that does not live on site happens to attend the daycare during the construction phases. The daycare risk is strictly for additional informational purposes.

Table 3 Project Construction Schedule						
	Phase 1		***Phase 2***		***Phase 3***	
Demolition	107 days	5 months	175 days	9 months	175 days	9 months

1.4 EXISTING CANCER RISK AND $PM_{2.5}$ CONCENTRATIONS

The City, in conjunction with the BAAQMD, has modeled the excess cancer risk and ambient $PM_{2.5}$ concentrations throughout the City. Sources contributing to the existing cancer risk and $PM_{2.5}$ concentrations include major roadways and stationary sources within the area. Major roadways include U.S. Highway 101 (U.S. 101) and Interstate 280 (I-280) freeways located approximately 1,200 feet west and 500 feet east of the project site respectively. Also Cesar Chavez Street, Potrero Avenue and Pennsylvania Avenue currently contribute to risk from roadways within the area. Stationary sources include those permitted by BAAQMD.

Stationary sources include known generators and gasoline stations as well as other manufacturing/ industrial sites that emit TACs. The closest permitted stationary sources include Yellow Cab, Inc., located at 1200 Mississippi Street (140 feet southeast of the project site); Dynamic Automotive, located at 1850 Cesar Chavez Street (approximately 380 feet south of the project site); Hong Kong Printing, located at 755 Pennsylvania Avenue (approximately 500 feet east of the project site); and Trayer Engineering Corp., located at 898 Pennsylvania Avenue (adjacent and east of the project site).

Table 4, Existing Cancer Risk and $PM_{2.5}$ Concentrations, shows the range of cancer risk and $PM_{2.5}$ concentrations for the project area as it relates to on-site residential, the on-site preschool and daycare facility, off-site residential and off-site school receptors within 1,000 feet of the project boundaries. The closer a receptor is to an emissions source, the greater the anticipated risk or $PM_{2.5}$ concentration.

Table 4 Existing Cancer Risk and $PM_{2.5}$ Concentrations				
	Cancer Risk (per million)		***$PM_{2.5}$ ($\mu g/m^3$)***	
	Minimum	***Maximum***	***Minimum***	***Maximum***
On-site residential receptors	10	34	8.2	8.7
On-site daycare/preschool receptors	17	24	8.3	8.4
Off-site residential receptors	8	74	8.2	10.0
Off-site school receptors	10	53	8.3	8.5

SOURCE: City of San Francisco, Citywide Air Pollution Modeling Files (December 2012).

1.5 SENSITIVE RECEPTORS AND LOCATIONS

Atkins evaluated the potential for adverse health effects associated with TAC exposures to residential and other sensitive receptors at and around the Project site. According to the BAAQMD sensitive "receptors are defined as people – children, adults, and seniors – occupying or residing in:

- Residential dwellings, including apartments, houses, condominiums
- Schools, colleges, and universities
- Daycares
- Hospitals
- Senior-care facilities"[3]

As discussed in Section 1.1, Project Background, p. 3, the Project area has residential and school/daycare land uses both on the project site and adjacent to it. The Project would be constructed in phases; therefore, construction impacts would only affect on-site receptors that are not located in the active construction phase. In addition, as construction finishes in one phase, new residential and daycare/preschool facilities would be occupied and become operational. Further, residents of the current housing units are anticipated to be relocated on site during construction of the various phases; therefore, it is assumed that all phases of development will be occupied when not under construction.

Off-site receptors consist of both schools and residential land uses. The closest school is Starr King Elementary School located approximately 60 feet west of the project site directly across Wisconsin Street. Residential land uses surround the project site to the west, west of Wisconsin Street, and to the north, north of 23rd Street and north of Phase 3 along both the east and west sides of Missouri Street. The nearest residential receptors are located adjacent to the Project boundaries, just east of Wisconsin Street. Additionally, there are residential land uses east of Texas Street and north of 25th Street that would be adjacent to the construction activities.

[3] BAAQMD, *Recommended Methods for Screening and Modeling Local Risks and Hazards* (May 2012).

CHAPTER 2 Criteria Air Pollutants

Criteria air pollutants are emitted from project-related construction and operational activities. Emissions are produced from both equipment and dust during construction activities. Operational emissions generated by Project implementation are primarily associated with mobile sources; however, natural gas usage, landscaping, maintenance, and stationary sources such as emergency generators also contribute to the emission of criteria pollutants.

2.1 CRITERIA AIR POLLUTANT ASSUMPTIONS AND METHODOLOGY

2.1.1 Construction Emissions

Criteria pollutant emissions associated with off-road construction equipment were estimated using emission factors from the 2011 OFFROAD program based on the anticipated construction year.[4] Emissions factors from on-road related construction equipment were taken from CalEEMod2007.[5] It is assumed that the same equipment is used for all construction phases, representing an average 2015 construction fleet. During construction, the following types of activities would be expected: abatement and demolition, site preparation and earthwork/grading, new infrastructure construction, and building construction. Some activities, such as building and coating could occur simultaneously. Demolition and construction activities would be limited to weekdays and daytime hours (7:00 a.m. to 7:00 p.m.). Figure 3, Construction Phasing, p. 8, shows the locations of the three Project phases. While the exact timing of the construction activities is unknown, there are three scenarios that represent the most likely order of construction. As detailed in Section 1.3, Project Phasing, p. 7, Scenario A would construct Phase 1 followed by Phase 2 followed by Phase 3. Scenario B would construct Phase 3 followed by Phase 1 followed by Phase 2, and Scenario C would construct Phase 3 followed by Phase 2 followed by Phase 1. All three construction scenarios were modeled based on the assumptions detailed in this report. The scenario with the greatest amount of construction emissions is presented.

Emissions were determined based on the number of residential units, square footage of non-residential buildings, acreage of the construction phase, and assuming a maximum of five-acres disturbed daily throughout grading activities. It was anticipated that construction would be conducted five days per week or 280 days per year. Annual emissions for each year of each phase were averaged over the duration of construction activities to determine average annual emissions. Average daily emissions were determined by summing the total emissions over the construction phase and dividing by the total number of days of

[4] Emissions associated with off-road equipment was calculated using the most current emission factors obtained from the 2011 OFFROAD Model to obtain an accurate picture of actual equipment and vehicle emissions.

[5] On-road emissions constitute soil hauling truck trips, vendor trips, and employee commute trips. On-road emissions are almost negligible compared to off-road construction emissions. Therefore, using the emission factors in the CalEEMod2007 Model, which may overestimate emissions from these vehicle trips, represents a conservative analysis of emissions from these sources.

construction. Modeling assumptions for construction, including equipment lists by phase, are detailed in Appendix B. CalEEMod output for off-site construction equipment is included in Appendix C.

2.1.2 Operational Emissions

Criteria pollutant emissions associated with the operation of the Project were estimated separately by phase using CalEEMod, in accordance with the BAAQMD's 2012 Guidelines, for the residential, retail, and community center development. Area source emissions from individual buildings were determined based on building size or number of units as appropriate to the land use. Further, based on confirmation from the Project Sponsor, there will be no fireplaces or wood burning stoves in any units. Mobile emissions associated with project-related vehicle operations used trip rates and vehicle trips identified in the project-specific transportation study.[6] No new public transportation services will be added as a result of Project implementation; however, some existing bus stops will be removed or consolidated and additional bus stops added to facilitate the new street lay-out of the Project. The traffic analysis takes into account the use of public transportation by Project tenants in developing the trip rates and average daily trips associated with the Project. The air quality analysis used the default CalEEMod trip lengths as the project-specific traffic study did not provide average trip lengths.

Criteria pollutant emissions from the proposed generator was calculated separately based on generator specific emissions as outlined in Appendix B. It is unknown what generator will be used on site as the timing for the construction and occupation of the community center is not known; therefore, it is unknown what generator requirements will be at that time. As a conservative estimate, Environmental Protection Agency (EPA) Tier 2 rated emission factors were used for the analysis, and the operational hours assumed were the maximum allowed for a standby generator under BAAQMD permitting regulations (50 hours per year).

Because 85 percent of the existing buildings are currently occupied, the net Project operational emissions are a result of the anticipated emissions for the Project minus the existing emissions from current on-site activities.

Because each Phase will become operational after construction is finished, emissions from subsequent construction activities are included as part of the interim year operational emissions for the Project. Interim years are the years between the completion of the first phase of construction and the completion of the last phase. Because it is unknown which Construction Scenario will be used, the Interim Year emissions reflect the maximum potential emissions during these years.

[6] CDM Smith. *Potrero HOPE Transportation Study*. July 11, 2012.

2.1.3 Localized Carbon Monoxide Emissions

Potential localized carbon monoxide concentrations were analyzed based on the BAAQMD's screening criteria using the 2030 cumulative with Project scenario which would have the greatest peak hour traffic. Therefore, impacts of traffic emissions from earlier years would be less than that for the 2030 cumulative year. According to BAAQMD criteria, a project's traffic would not have the potential to result in adverse impacts if:

- A project is consistent with an applicable congestion management program established by the county congestion management agency for designated roads or highways, regional transportation plan, and local congestion management agency plans.
- The project traffic would not increase traffic volumes at affected intersections to more than 44,000 vehicles per hour.
- The project traffic would not increase traffic volumes at affected intersections to more than 24,000 vehicles per hour where vertical and/or horizontal mixing is substantially limited (e.g., tunnel, parking garage, bridge underpass, natural or urban street canyon, below-grade roadway).

If any of the above criteria are not met a quantitative analysis of CO emission impacts on the local project vicinity would need to be conducted.

2.2 CONSTRUCTION CRITERIA AIR POLLUTANTS

Emissions from construction activities typically result from material handling, traffic on unpaved or unimproved surfaces, demolition of structures, removal of debris, use of paving materials and architectural coatings, exhaust from construction worker vehicle trips, and exhaust from diesel-powered construction equipment.

Construction emission estimates for the Project are summarized by Phase in Table 5, Project-Level Construction Emissions, p. 16. As detailed in Section 1.3, Project Phasing, p. 7, the Project would be constructed in three non-overlapping phases, using one of three Construction Scenarios. Emissions were estimated for Scenarios A, B, and C and the worst-case emissions for each criteria pollutant are presented in Table 5. This worst-case scenario is Scenario C, which would construct Phase 3, followed by Phase 2, followed by Phase 1.

The daily emissions analysis assumes that the same construction equipment would be used for all phases of development; therefore, emission estimates would change based on the type of equipment on site and the construction activities that take place during a given day and not the age of the fleet.

While the Development Phases will not overlap on any given day, one Phase may end and the next start in any given year. Further, while the equipment would be the same regardless of Development Phase, the total level of activity per year would vary based on the Development Phase or sub-phases under construction in that year. Therefore, annual emissions for each year would vary with the Construction Scenario implemented. The reported annual emissions represent the maximum emissions possible for that year and this worst-case scenario is construction Scenario C.

Table 5 Project-Level Construction Emissions

	ROG	NO_X	PM_{10}	$PM_{2.5}$
Daily Construction Emissions (lbs/day)				
Phase 1 Average	4.10	47.22	1.91	1.72

Combined Annual[b]	1.04	12.02	0.50	0.45

SOURCE: Atkins (2013).

a. Combined Daily is the average daily emissions over the entire 10.33-year construction period.

b. Combined Annual is the average annual emissions over the entire 10.33-year construction period.

Table 5, Project-Level Construction Emissions, p. 16, shows the emissions by Development Phase as well as modeled year of construction. As shown, NO_X emissions for all phases of construction would be relatively high. Assumptions and calculations used in the modeling are included in Appendix B.

2.2.1 Measures to Reduce Construction Emissions

High NO_X levels predominantly are the result from off-road construction equipment and on-road vehicle exhaust. Reduction measures have been identified that would reduce the NO_X emissions associated with construction equipment exhaust. The reduced worst-case Combined Daily emissions are presented (Construction Scenario C) along with the maximum daily emissions per year for each of the Development Phases under Construction Scenario C in Table 6, Reduced Project-Level Construction Emissions, p. 18. This analysis provides construction criteria air pollutant emissions with implementation of reduction measures RM-1 and RM-2. Implementation of RM-1 would be necessary to reduce emissions for the first two years of construction (2015 and 2016). Beginning in 2017 and extending for the entire duration of construction activities, RM-2 would be necessary to reduce construction emissions. Assumptions and Calculations are included in Appendix B.

RM-1 All off-road construction equipment greater than 50 hp shall have engines that meet or exceed USEPA or ARB Tier 3 off-road emission standards, or the Project Sponsor must prepare a construction emissions minimization plan designed to reduce NO_X by a minimum of 39 percent from Tier 2 equivalent engines.

RM-2 For all construction occurring after 2016, all off-road construction equipment greater than 50 hp shall have engines that meet or exceed USEPA or ARB Tier 4 interim off-road emission standards, or the Project Sponsor must prepare a construction emissions minimization plan designed to reduce NO_X by a minimum of 21 percent from Tier 3 equivalent engines.

2.3 OPERATIONAL CRITERIA AIR POLLUTANTS

Operational emissions generated by both stationary and mobile sources would result from normal day-to-day activities within the Project area. Area source emissions would be generated by the consumption of natural gas for space and water heating devices, and the operation of landscape maintenance equipment. Mobile emissions would be generated by the motor vehicles traveling to, within, and from the project site. Because the operation of the first two completed phases would overlap with the construction the remaining phases, the emissions from construction activities are combined with the operational emissions during the interim year emissions for the Project. Because it is unknown as to which order the Project Phases will be constructed, the interim year estimates represent the maximum potential interim year construction emissions from all scenarios.

a. PM_{10} and $PM_{2.5}$ emissions include the reductions from RM-3 Outlined under Section 3.5, Results of Project Analysis, p. 32.

b. Combined Daily is the average daily emissions over the entire 10.33-year construction period.

c. Combined Annual is the average annual emissions over the entire 10.33-year construction period.

Table 7, Criteria Air Pollutant Emissions, shows the existing emissions from construction activities and project operations during Interim Years. Therefore, for each Interim Year the highest pollutant emissions are reported. This represents a conservative analysis because depending on the Development Scenario implemented some interim year emissions will be less than reported here. The modeling assumptions and calculations are included in Appendix B and the CalEEMod output is included as Appendix D (Project) and Appendix E (Existing).

SOURCE: Atkins, CalEEMod modeling output (2013).

a. Net operational build-out is the sum of the operational emissions from all Project Phases and the generator minus the emissions from existing land uses. It represents the anticipated daily or annual emissions after the completion of all construction activities

b. Under the worst-case development scenario, during years 2015 and 2016, only emissions from construction of the first phase (whether it be Phase 1 or 3) would occur. Note: Under none of the construction scenarios would Phase 2 be developed first.

c. Under the worst-case development scenario, during years 2017 and 2018, only emissions from construction of the first phase would occur if Phase 3 is developed first. If Phase 1 is developed first emissions from these years include the construction activities from subsequent construction phases and the operational activities from the operation of Phase 1.

d. Emissions for Interim Years 2019 through 2025 include emissions from construction activities from subsequent phases and operational activities from operations of previous development phases. For each year, the greatest amount of emissions is reported, regardless of the development scenario. This represents a conservative analysis as depending on the Development Scenario implemented some interim year emissions will be less than reported here.

Measures to Reduce Operational Criteria Pollutant Emissions

High NO_X levels are mainly the result of off-road construction equipment and on-road construction vehicle exhaust, combined with the emissions from the operation of the occupied Phases. Implementation of RM-1 and RM-2 would reduce NO_X emissions from construction activities. Table 8, Reduced Criteria Air Pollutant Emissions, provides operational criteria air pollutant emissions with implementation of the construction reduction measures.

2.4 LOCALIZED CARBON DIOXIDE EMISSIONS

The implementation of the Project would increase traffic within the local area. Under the cumulative plus Project scenario, the intersection of Cesar Chavez and Pennsylvania Avenue at the NB I-280 off ramp would have the greatest amount of traffic. Total cumulative (2030) peak hour traffic is estimated at 4,320 vehicles.[7] Traffic at this intersection and all other studied in transportation analysis for earlier years are all below this amount.

According to the project-specific transportation study, all of the study intersections would operate at an acceptable LOS D or better under the Existing Plus Project scenario. Further, the Project would not result in congestion impacts for freeways or freeway segments. Therefore, the Project-related traffic increases would be consistent with regional transportation plans.

According to the BAAQMD screening criteria, if a project-impacted intersection has greater than 44,000 vehicles per hour, or 24,000 vehicles per hour where there is limited vertical and/or horizontal mixing, there is the potential for that project to adversely impact the CO levels in the local vicinity. The traffic study shows that the cumulative traffic volumes (4,320 vehicles per hour maximum) would be below these levels and that the Project traffic is consistent with the regional transportation plans. Therefore, the Project does not require a quantitative CO analysis.

[THIS PAGE INTENTIONALLY LEFT BLANK]

CHAPTER 3 Health Risk Assessment

Atkins evaluated the potential for adverse health effects associated with toxic air contaminant exposures to residential and other sensitive receptors at and around the project site. This section of the report presents a health risk analysis for on-site and off-site sensitive receptors resulting from implementation of the Project. This health risk assessment discusses the anticipated excess cancer risk (risk) and $PM_{2.5}$ concentrations for on-site and off-site receptors resulting from the construction of the three phases, operation of a new on-site generator, and the increased traffic within the project area.

3.1 EMISSIONS ESTIMATES

3.1.1 Construction

Off-Road Equipment

The detailed list of construction equipment was provided by the project sponsor for each phase including the horsepower and hours of operation for each piece of equipment. 2011 OFFROAD emission factors were used to estimate the average daily and annual emissions for each construction phase for the entire Project, as detailed in Table 5, Project-Level Construction Emissions, p. 16, and Table 6, Reduced Project-Level Construction Emissions, p. 18. The detailed construction list and the equipment and calculations are included in Appendix B.

On-Road Heavy-duty Trucks

On-road truck emissions were calculated using the estimated total number of vender import, material import and material export vehicles. Because the exact haul route is unknown, and there are two major freeways close to the project site, emissions were estimated for three haul scenarios. As a conservative approach to the analysis, the maximum risk and $PM_{2.5}$ concentration of the three haul routes combined with the off-road equipment emissions were used to determine Project and cumulative risk and $PM_{2.5}$ concentrations. The three hauls route scenarios are as follows:

1. 100 percent of the haul trips would exit the U.S. 101 freeway at Cesar Chavez, travel along Cesar Chavez to Connecticut Street then travel north along Connecticut Street and access the project site from Connecticut Street, 25th Street, or Texas Street depending on the Phase.
2. 100 percent of the haul trips would exit the I-280 freeway at Pennsylvania Avenue, travel south along Pennsylvania Avenue to 25th Street and access the project site from 25th Street, Texas Street or Connecticut Street depending on the Phase.
3. 50 percent of the haul trips would access the site from the U.S. 101 as identified under haul route one and 50 percent would access the site from the I-280 as identified under haul route two.

Worker Commuting Vehicles

The estimated number of worker trips depends on the development phase but is less than 200 trips per day. Existing traffic along the major roadways is between 13,000 and 18,000 trips per day. Further, the

worker commute trips are less than the project-related trips at build-out for these major roadways. As the number of daily construction worker commute trips is less than the project-related traffic trips, the health risk associated with the construction worker trips would be less than that estimated for Project trips. Therefore, the potential for health risk impacts related to worker trips are not specifically evaluated in this analysis.

3.1.2 Operational

Project-Related On-Road Mobile Sources

CDM prepared the traffic study and provided average daily vehicle trips for local roadways under existing and Project build-out conditions. Based on the information presented in the traffic study, two roadways within 1,000 feet of the project site exceed 10,000 vehicles per day, the volume below which the BAAQMD has determined that traffic would have little impact. These roadways are Cesar Chavez Street located 500 feet south of the project site and Pennsylvania Avenue located approximately 550 feet east of the project site. Potrero Avenue, while greater than 1,000 feet from the project site, was located within the study area and exceeds the 10,000 vehicle per day level; therefore, it was also included in the analysis. Potrero Avenue is located 2,200 feet west of the project site and west of the U.S. 101 freeway. Emissions factors for project-specific traffic along these three roadways were determined using BAAQMD Methodology.[8] The weighted average of the 70-year emissions were determined for diesel particulate matter (DPM) and total organic gases (TOG) using EMFAC2011 and the light duty auto, light duty truck 1, light duty truck 2, and motorcycle (LDA, LDT1, LDT2, and MCY) vehicle categories for gas and diesel vehicles. Assumptions and calculations are included in Appendix F.

Project-Related Stationary Sources

As part of the Project, a generator would be installed at the community center. Project-specifics as to exact location within the community center grounds and the type of generator were not available at the time of modeling. Therefore, the following assumptions were made. The generator would be located at the southeast corner of the community center property as the wind is predominately from the northwest, this places the generator directly upwind of residential sensitive receptors. The generator is assumed to be an EPA Tier 2 engine with a horsepower of 1,100 and would be operating for the full permitted 50 hours per year. Assumptions with respect to the generator are included in Appendix B and Appendix F.

Other Near-by Sources

To identify areas within the City most affected by TACs, the City of San Francisco in conjunction with the BAAQMD has inventoried and assessed air pollution exposure from mobile, stationary, and area sources within the City. Within just over 1,000 feet of the project site, there are several sources, which have been included in the Citywide modeling and are, therefore, taken into account with respect to the cumulative health risk analysis. The following sources are some of the primary sources within the analysis study area.

[8] BAAQMD, *Recommended Methods for Screening and Modeling Local Risks and Hazards* (May 2012).

Roadway Sources. The I-280 freeway is located 880 feet east of the project site and the U.S. 101 freeway is located 1,100 feet west of the project site.

Stationary Sources. Permitted stationary sources within 1,000 feet of the project site include two fueling facilities and seven other industrial or commercial permitted sources outlined in Section 1.4, Existing Cancer Risk and $PM_{2.5}$ Concentrations, p. 11. These sources are located to the south and east of the project site.

3.2 ESTIMATED AIR CONCENTRATIONS

Methodologies used to evaluate emissions for the Project and cumulative health risk were based on the most recent BAAQMD Protocol,[9] and consultation with City of San Francisco Environmental Planning Staff. Cancer risk in this report is based on DPM concentrations from diesel exhaust and total organic gases from gasoline fueled equipment and vehicles. Diesel particulate exhaust is a complex mixture of hundreds of individual chemicals. DPM is the main constituent and regulatory guidelines use it as a surrogate measure of carcinogen exposure from diesel exhaust. For gasoline exhaust a speciation profile of pollutants was obtained from BAAQMD.[10] Based on BAAQMD methodology, DPM emissions are estimated using $PM_{2.5}$ emission factors.

3.2.1 Modeled Sources

USEPA's AERMOD model was used to determine concentrations for project-specific construction and operational sources. AERMOD requires a variety of input parameters as outlined below. When specific information is unavailable, default values are used to estimate a worst-case, conservative analysis. The following parameters were used in the AERMOD modeling.

Meteorological Data. Meteorological data for use in the modeling was obtained directly from the BAAQMD and uses data for the Mission Bay station for 2008. This meteorological data was used for consistency with the Citywide modeling.

Terrain Data. Elevation and land use data would influence the concentrations at each receptor. Terrain data was imported as a USGS DEM 1, degree file for the San Francisco East quadrant. Because the Project is located within the City of San Francisco, the modeling uses urban coefficients with a population of 818,826 as indicated from the San Francisco County 2011 Census.

Emission Rates. Emission rates for on-site construction activities were derived from the 2011 OFFROAD emissions factors. Off-site haul truck emissions rates during construction were determined by CalEEMod modeling. The emissions factor for the generator was derived based on the anticipated emissions from an EPA Tier 2 rated diesel engine with 1,100 horsepower and operating 50 hours per year. Emission factors for the vehicles along major roadways use EMFAC2011 emission rates from the LDA, LDT, and MCY vehicle classes as those would be the most common vehicles associated with the Project. Roadway emissions were calculated based on the Project-related vehicles and not overall

[9] BAAQMD, *Recommended Methods for Screening and Modeling Local Risks and Hazards* (May 2012).
[10] BAAQMD, *Recommended Methods for Screening and Modeling Local Risks and Hazards* (May 2012).

roadway volumes, as these are already included in the Citywide model. Emissions factors used in the modeling are as follows (Table 9, Project Emissions Factors).

Table 9 Project Emissions Factors

Values may not add due to rounding.
N/A = Means the emission factor is not appropriate for that source.
a. Roadway emission factors are based on the project specific traffic volumes.

Source Parameters. Source locations and parameter information are required to accurately model the dispersion of emissions. The following discusses source locations and parameters by construction and operational sources.

Construction: During construction there would be multiple emission sources associated with the movement of equipment within the construction site. On-site construction vehicle emissions were modeled as surface based line sources with plume width of 10.5 meters, plum height of 9.14 meters, and a release height of 4.57 meters. Haul trips are modeled using line sources with a plume height of 9.14 meters and plume width based on roadway width. As discussed previously, haul trips would occur on Cesar Chaves Street, Connecticut Street, 25th Street, Pennsylvania Avenue and Texas Street. Therefore, for Cesar Chavez Street plume width is 23 meters, Connecticut Street and 25th Street at 10 meters, Pennsylvania Avenue is nine meters, and Texas Street is five meters.

Operational: Project-related operational emissions result from project-specific traffic along local roadways and the generator. Source parameters for the roadways and generators are as follows.

Roadways were modeled as surface based volume sources. Release height is 0.492 meter as all project-related traffic would be comprised of passenger vehicles. Plume height is 3 meters, and plume width is based on roadway width. Therefore, for Cesar Chavez Street plume width is 23 meters, Pennsylvania Avenue is nine meters, and Potrero Avenue is 26 meters.

The generator was modeled as a point source with a release height of 1.99 meters. The location of the generator is identified on Figure 4, Receptor Grids, p. 28. Gas exit temperature is 948.7°F. Stack inside diameter is 0.203 meter. Gas exit flow rate is 5,611.5 m^3/s.

Receptors: As discussed in Section 1.1, Project Background, p. 3, the Project area has residential and daycare/preschool land uses both on the project site and adjacent to it. Land uses to the north and west of the project site are predominantly residential and school uses and are, therefore, considered sensitive receptors. Land uses to the south are commercial and industrial land uses and are not considered sensitive receptors. To the east of the project site is a mixture of residential, school, and commercial and industrial land uses; therefore, some receptors east of the school are considered. Figure 4, Receptor Grids, p. 28, illustrates the location of off-site sensitive receptors. The closest off-site sensitive receptors are located directly adjacent to the project site to the west as well as to the east across Wisconsin Street. To the north, the closest sensitive receptors are directly north of Dekota Street and 22nd Street. To the east, the closest sensitive receptors are located directly across Texas Street.

Because the on-site residents will be moved from one phase to another, risk to these receptors would be cumulative and this analysis accounts for risk from construction as well as operation, similar to the potential risk to the off-site receptors that would be occupied and operational during all three phases of construction. Currently there is a daycare/preschool facility located at 71 Turner Terrace which is in Project Phase 3. While this specific receptor location will cease to exist after the construction of Phase 3, an on-site daycare/preschool facility will be operational during all three phases of construction. If Phase 3 is constructed first, the daycare will move to a portable facility located within the northeastern portion of Phase 1. Subsequent to the completion of Phase 3 construction, the daycare will either remain in the same location on Phase 1 or will be moved back to Phase 3 until the project-specific daycare location is constructed. The new project-specific daycare/preschool facility will be located within the community center located southeast of the future corner of Arkansas Street and 24th Street, in the center of Phase 2. Under Scenario A, the daycare/preschool facility will remain at the existing location until the completion of Phase 2 construction and then will move to its permanent location during the construction of Phase 3.

FIGURE 4

Receptor Grids

ATKINS

100017266

Potrero Hope SF Master Plan

To evaluate the risk to all off-site sensitive receptors, a 20-meter by 20-meter receptor grid was implemented over the entire area from southwest of the intersection of Cesar Chavez Street and Bryant Street to northeast of 20th Street and Illinois Street, creating a project area radius of over 1,000 feet around the project site.[11] Because there would be people living on the project site during construction activities a 10-meter by 10-meter receptor grid was implemented from the intersection of 26th Street and Wisconsin Street to the intersection of Texas Street and 22nd Street. This smaller grid provides a more extensive evaluation of on-site impacts. Figure 4, Receptor Grids, p. 28, depicts the receptor grids as well as illustrates the known locations of the existing and project-specific daycare, school receptor locations and residential receptor areas.

While one phase of the proposed project is being constructed, existing residents would be moved to other areas of the site. Once construction within one phase is completed, those residents located in the other phases would be relocated to the new housing units, as eligible. Therefore, during construction of any given phase, the two phases that are not currently undergoing construction would be assumed to be occupied with either the existing or future receptors. Because the majority of the Project would be comprised of residential and/or daycare/preschool land uses the entire project site is treated as sensitive receptors for modeling purposes. It is assumed that for the most part, residents will not relocate after the completion of construction, so that if a resident is located in Phase 1 during the final phase of construction, they will remain in Phase 1 for the remainder of the 70-year risk analysis period.

3.3 RISK CHARACTERIZATION METHODS

Cancer risk is calculated from the annual average concentrations as derived from AERMOD modeling. After the modeled concentrations were converted to project-specific concentrations by multiplying the modeled concentrations by the project-specific emission factors, they were converted into cancer risk. The following equation was used to determine the associated cancer risk:

$$\text{Cancer Risk} = \text{Inhalation Dose (mg/kg-day)} * \text{Cancer Potency (kg-day/mg)} * (1 \times 10^{6}) * \text{ASF}$$

The Cancer Potency is the potential risk of developing cancer per unit of average daily dose over a 70-year residential lifetime. Cancer Potency is 1.1 kg-day/mg. The 1×10^{6} is used to express the risk per million people.

The inhalation dose for DPM was determined by the following equation:

$$\text{Dose} = (C * DBR * A * EF * ED * 10^{-6}) / AT$$

Where:

Dose = Dose through inhalation (mg/kg/day)

10^{-6} = Micrograms to milligram conversion and liters to cubic meters conversion.

C = Concentration in air ($\mu g/m^3$)

DBR = Daily Breathing Rate (L/kg bodyweight – day) (302 – 80th percentile for residential; 581 school/daycare)

[11] While the scope of work states a 1 km radius would be used, the level of impacts at 1,000 feet does not warrant expanding the radius any further.

A = Inhalation absorption factor (1)

EF = Exposure frequency (construction/school 260 days per year, residential 350 days per year)

ED = Exposure duration (years):

Construction		*Operational*	
Phase 1:	2.33	Residential:	70
Phase 2:	4	School/daycare:	9
Phase 3:	4		

AT = Averaging time period over which exposure is averaged (days) (25,550 days)

ASF = Age sensitivity factor (also known as CRAF)

Construction		*Operational*	
Resident Child	10/3[12]	Residential:	1.7/1[13]
School:	3	Daycare/preschool:	10/3
Daycare:	10/3		

Because of the duration of construction, construction risk was analyzed assuming a child was born at the beginning of construction and, therefore, would still be a child at the completion of construction. Therefore, the residential ASF uses the child values of 10 and 3 rather than the adult value of 1.7.

3.3.1 Construction Risk

There are three potential Construction Scenarios, as detailed in Section 1.3, Project Phasing, p. 7. Construction of individual Project Phases would occur at different times under different scenarios. The three Construction Scenarios analyzed are summarized as follows:

- Scenario A: Constructs Phase 1, then Phase 2, then Phase 3
- Scenario B: Constructs Phase 3, then Phase 1, then Phase 2
- Scenario C: Constructs Phase 3, then Phase 2, then Phase 1

Without reduction measures the risk for each Development Phase would remain the same regardless of the Construction Scenario chosen because the analysis assumes that all equipment would be EPA Tier 2 equipment regardless of the year. With the implementation of reduction measures, the emissions for the on-site construction vehicle fleet would change throughout the 10-year Project construction. This is because the reductions would implement stricter emissions requirements based on the construction year and, therefore, would result in different levels of risk based on the timing of construction for the individual Construction Phase and the reduction measures' implementation.

[12] The Age sensitivity factor of 10 is used for construction periods of approximately 2 years as children could possibly be exposed to all of the construction emissions between birth and 2 years of age. The age sensitivity factor of 3 is used for construction periods greater than 3 years as children would be exposed partially at a younger age and partially when their lungs are more developed after the age of 2.

[13] For Operational Emissions, the ASF for emissions from vehicles is 1 as the age sensitivity factor is included in the Project-specific emission factor. The ASF for the generator however, requires the use of the ASF of 1.7 to accommodate the increased risk for an individual that is a child during part of the 70-year timeframe.

Individuals would relocate on site during Project construction based on their initial location and the Construction Scenario implemented. Specifically for the analysis it was assumed that while Phase 1 is being conducted the on-site residents will be located in Phase 2 or Phase; when Phase 2 is being constructed residents will be in Phase 1 or Phase 3, and when Phase 3 is constructed residents will be in Phase 1 or Phase 2. This results in 24 distinct variations of receptor locations throughout the construction timeframe (eight associated with each Construction Scenario). Risk was analyzed for each of these 24 combinations; however, only the most conservative risk (i.e., worst case) is reported in this analysis. The results from the risk analyzed for all other combinations are included in Appendix G.

Additionally, while we can determine what Phase a resident may potentially move to, it is unknown where within that Phase the person would be located. It is highly unlikely that a person would move from the location of highest exposure in one phase to the location of highest exposure in both of the other phases. Therefore, reporting the maximum risk will greatly overestimate potential risk to on-site receptors. In order to report a reasonably conservative risk, results are reported as a range. Risk was identified for each Development Phase within each of the three Construction Scenarios; however, only the range with the greatest risk is reported in this analysis. The lower end of the risk range identified is the mean risk for a given Development Phase within the given Construction Scenario, and the higher end of that range is represented by the mean plus one standard deviation.

The daycare center,[14] similar to the residential receptors, would relocate throughout the 10-year construction period as detailed in Section 1.3, Project Phasing, p. 7. However, there are only three potential scenarios to represent the relocation of the daycare on site. Under Scenario A risk for the daycare was determined by the risk associated with the existing facility and the range of risk associated with the potential location of the new receptor in Phase 2. Under Scenario B, risk was based on the range associated with the potential locations in Phase 1 and potential locations in Phase 3. Under Scenario C, risk was based on the range associated with the potential locations in Phase 1 and final location in Phase 2.

3.3.2 Operational Risk

Operational Risk results from the generator emissions and emissions as a result of increased traffic from the Project. Traffic levels along the roadways would increase relative to the level of on-site operations. Therefore, traffic along these roadways would be anticipated to be lower during construction than once construction is completed and all new on-site residential and non-residential land uses are operational. However, as a conservative estimate, risk was calculated based on the total increase after the build-out of the Project is complete. Roadway risk is analyzed for three roadways (Cesar Chavez Street, Pennsylvania Avenue, and Potrero Avenue). For off-site receptors the reported operational roadway risk is the total of risk from the three roadways for the residential and school receptors that are also exposed to the greatest construction risk. This value reports the expected risk for the maximally exposed receptor. For on-site

[14] Note that it is anticipated that children living within the Project boundaries would be the only children attending the daycare. Therefore the maximum risk to these children would be represented by the Resident risk and is not a combination of the resident risk and the daycare risk. The daycare risk is provided to show potential risk in case an individual that does not live on site happens to attend the daycare during the construction phases. The daycare risk is strictly for additional informational purposes.

receptors, the operational roadway risk was determined independently for each Development Phase. Because roadway risk is relatively small compared to construction risk, the roadway risk reported in this analysis is the roadway risk associated with the receptor location (residential and daycare) that is also exposed to the greatest construction risk and, therefore, results in the maximally exposed receptor for overall project risk.

Emissions from the generator are estimated to be consistent from the beginning of operation throughout the analysis period of 70 years. Therefore, risk for off-site and on-site receptors with respect to the generator is determined in the same way as the roadway risk.

3.3.3 Total Project Risk

Total Project risk is the sum of the construction and operational risk for the on-site and off-site receptors. This is the range of excess cancer risk that could be expected over a 70-year lifetime for residential and a nine-year exposure duration for student and daycare receptors as a result of the project's emissions.

3.3.4 Cumulative Risk

Cumulative risk is the sum of the total Project risk and the background risk at the project site. The background risk is derived from the Citywide modeling database and for on-site receptors this is reported as the maximum risk from all locations within the Phase the receptor was located in at the end of construction. For off-site receptors the reported risk is the specific risk associated with the receptor that would be exposed to the maximum project-related risk.

3.4 $PM_{2.5}$ CHARACTERIZATION METHODS

$PM_{2.5}$ concentrations are based on annual averages. These $PM_{2.5}$ concentrations will vary throughout the construction period. However, as a conservative estimate, the total Project concentrations of $PM_{2.5}$ are reported as a combination of the annual emissions at the location of the receptor during the last phase of construction and the concentrations from operation. Upon full build out, $PM_{2.5}$ concentrations would decrease as construction activities would cease.

Cumulative $PM_{2.5}$ concentrations are the combination of the total Project concentrations (from both construction and operational sources) plus the background concentrations derived from the Citywide modeling. As with the background risk, background $PM_{2.5}$ concentrations for on-site receptors is reported as the maximum concentration determined for all locations within the phase the receptor was located in at the end of construction. For off-site receptors the reported concentration is associated with the receptor that is exposed to the maximum project-related concentration.

3.5 RESULTS OF PROJECT ANALYSIS

The intensity and level of construction activity has the potential to increase health risk in an area due to the exposure to construction emissions. As discussed in Section 2.1.1, Construction Emissions, p. 13, Project construction is anticipated to last approximately 10 years. This long-term continued exposure of

area residents, schools, and daycares (both on and off site) to diesel-powered construction equipment and haul trucks has the potential to increase cancer risk and $PM_{2.5}$ exposure levels on the project site and in the project vicinity. Operational activities, such as the operation of the emergency generator and the increase in vehicle traffic from the proposed Project has the potential to increase cancer risk and $PM_{2.5}$ exposure levels on the project site and in the project vicinity as well.

Modeling assumptions for the health risk assessment are included in Appendix F. Risk and $PM_{2.5}$ calculations are included as Appendix G. Output from the AERMOD model is included as Appendix H for construction and Appendix I for operational concentrations.

3.5.1 Project-Related Health Risk

Total Project risk is the sum of the construction, roadway and stationary source risk as described in Section 3.3, Risk Characterization Methods, p. 29. As detailed in Section 1.3, Project Phasing, p. 7, the Project would be constructed in three non-overlapping phases, using one of three Construction Scenarios. For off-site receptors the risk was estimated for Scenarios A, B, and C and the maximum risk identified for a single location is reported. Typical risk methodology assumes that the residents/students at a receptor when construction starts would be the same residents/students at that receptor when the exposure duration ends (i.e., 70 years for residents and nine years for students). For on-site receptors, a simple maximum risk scenario is not appropriate. Although the exposure duration remains the same, the development schedule for the Project assumes that the sensitive receptors will change locations throughout construction.

Risk to on-site receptors will change based on the location of the receptor and the Development Phase being constructed. For example, for residential receptors during the construction of Development Phase 1, receptors located on the southern edge of Development Phase 2 would be exposed to a higher risk than those in along the northern of Phase 2 or located in Phase 3, and there would be no risk for Phase 1 since no one would be residing there during construction. Similarly when Development Phase 3 is under construction, receptors on the northern edge of Phase 2 would be exposed to greater risk levels than those along the southern portion of Phase 2 or located in Phase 1. Risk for on-site residential receptors was reported as the greatest range of risk from all 24 Development Combinations. These Development Combinations were determined based on the Development Scenario (A, B, or C) and the re-location scenarios possible for each of the three Development Scenarios. For the on-site daycare receptors there are only three Development Combinations and those are based on the Development Scenario implemented.

The determination of an accurate risk for on-site receptors is further complicated by the fact that residents may move several times throughout Project development. This means that residents *(a)* may move to a location of high risk during the construction of one Development Phase but to an area of minimal risk during another; *(b)* always be moved to a location of minimal risk; or *(c)* always move to a location of higher risk. Further, there is only one receptor location in each Development Scenario that will result in maximum risk exposure and it is highly unlikely that a receptor will be re-located in the area with the greatest level of risk during each construction phase. This is due to the fact that re-location on site is anticipated to be staged such that the residents will have to move a minimum number of times. For example, if a person is living in Phase 3, and Construction Scenario A is implemented, that resident most

likely would remain in the same location in Phase 3 during the construction of Development Phase 1 and Development Phase 2 before being moved out of Phase 3. Therefore, that receptor would not be at the location of greatest risk during construction of Development of Phase 1.

Another complication is that the analysis reports risk based on the worst-case construction scenario. Meaning the risk is based on the greatest level of emissions that would occur during construction. This in and of itself results in a conservative risk; however, when combined with the relocation element, it makes the use of a maximum cancer risk determination for on-site receptors excessively high and therefore does not present an accurate analysis of the potential impacts of the project. Therefore, in order to provide a conservative, yet reasonable, risk analysis a range was identified. The reported risk range for on-site receptors is the greatest range identified for all potential Development Scenario Combinations[15] and is represented by the mean and the mean plus one standard deviation. The mean cancer risk is sum of the average risk for each of the three Development Phases a residence or school receptor is located during Project construction. The mean plus one standard deviation will provide a conservative maximum level of risk, which is a more accurate representation of a worst-case scenario considering the combination of project variables.

Table 10, Project-Related Risk, p. 35, reports the range of cancer risk as it relates to the greatest exposed on-site residential, on-site daycare/preschool uses, off-site residential and off-site school receptors within 1,000 feet of the project boundaries. For off-site receptors, the reported risk represents a single location as designated by the number and Universal Transverse Mercator (UTM) coordinates. On-site receptor risk is reported for the Development Scenario with the greatest risk range for the Project. For residential receptors the maximum risk would be experienced under Development Scenario A when a receptor is located in Phase 2 during the construction of Phase 1, in Phase 1 during the construction of Phase 2 and in Phase 2 during the construction of Phase 3. For the daycare site, exposure to the maximum risk would also be experienced during Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3.

The maximally exposed individual sensitive receptor (MEISR) for each off-site receptor type is shown on Figure 5, Project Risk MEISR, p. 36. Because people will relocate to various locations throughout the project site, an MEISR cannot be identified for on-site receptors. However, in Table 10, Project-Related Risk, p. 35, shows that project-related cancer risk for on-site residential uses would range from about 103 to 169 excess cancer risk. The majority of the anticipated cancer risk is a result of construction emissions. Risks from operational sources (project generated vehicle trips and the emergency back-up generator) would be negligible in comparison.

[15] A Development Phase Combination is a potential order that a resident would move during development. For example, during Development Scenario A, the resident could stay in Phase 3 during the construction of Phase 1 and Phase 2 and then be moved to Phase 2 while Phase 3 is developed.

3.5.2 Measures to Reduce Construction Risk

High risk levels associated with construction of the proposed Project is the result of $PM_{2.5}$ emissions from the off-road construction vehicles. Implementation of RM-2, as described in Section 2.2.1, Measures to Reduce Construction Emissions, p. 17, would reduce $PM_{2.5}$ from later construction periods because Tier 4 equipment includes a diesel particulate filter and is the best available control technology for $PM_{2.5}$ emissions control. However, the initial construction phase would still result in higher levels of risk as Tier 3 engines do not reduce particulate emissions over the reduction attributed to Tier 2 engines. Therefore, the implementation of RM-3 would further reduce risk to on-site and off-site receptors for the initial construction phase. Table 11, Reduced Project-Related Risk, p. 39, provides project-related risk with the implementation of RM-2 and RM-3.

RM-3 A. Construction Emissions Minimization Plan. Prior to issuance of a construction permit, the project sponsor shall submit a Construction Emissions Minimization Plan (Plan) to the Environmental Review Officer (ERO) for review and approval by an Environmental Planning Air Quality Specialist. The Plan shall detail project compliance with the following requirements:

1. All off-road equipment greater than 25 hp and operating for more than 20 total hours over the entire duration of construction activities shall meet the following requirements:
    a. Where access to alternative sources of power is available, portable diesel engines shall be prohibited;
    b. All off-road equipment shall have:
        i. See RM-1 and RM-2
        ii. Engines that are retrofitted with an ARB Level 3 Verified Diesel Emissions Control Strategy (VDECS).[16]
    c. Exceptions:
        i. Exceptions to A(1)(a) may be granted if the project sponsor has submitted information providing evidence to the satisfaction of the ERO that an alternative source of power is limited or infeasible at the project site and that the requirements of this exception provision apply. Under this circumstance, the sponsor shall submit documentation of compliance with A(1)(b) for on-site power generation.
        ii. Exceptions to A(1)(b)(ii) may be granted if the project sponsor has submitted information providing evidence to the satisfaction of the ERO that a particular piece of off-road equipment with an ARB Level 3 VDECS is (1) technically not feasible, (2) would not produce desired emissions reductions due to expected operating modes, (3) installing the control device would create a safety hazard or impaired visibility for the operator, or (4) there is a compelling emergency need to use off-road equipment that are not retrofitted with an ARB Level 3 VDECS and the sponsor has submitted documentation to the ERO that the requirements

[16] Equipment with engines meeting Tier 4 Interim or Tier 4 Final emission standards automatically meet this requirement, therefore a VDECS would not be required.

of this exception provision apply. If granted an exception to A(1)(b)(ii), the project sponsor must comply with the requirements of A(1)(c)(iii).

iii. If an exception is granted pursuant to A(1)(c)(ii), the project sponsor shall provide the next cleanest piece of off-road equipment as provided by the step down schedules as follows

1. Compliance Alternative 1: Engine Emission Standard 2 with ARB Level 2 VDECS
2. Compliance Alternative 2: Engine Emission Standard 2 with ARB Level 1 VDECS
3. Compliance Alternative 3: Engine Emission Standard 2 with alternative fuels. (Alternative fuels are not VDECS).

If the requirements of (A)(1)(b) cannot be met, then the project sponsor would need to meet Compliance Alternative 1. Should the project sponsor not be able to supply off-road equipment meeting Compliance Alternative 1, then Compliance Alternative 2 would need to be met. Should the project sponsor not be able to supply off-road equipment meeting Compliance Alternative 2, then Compliance Alternative 3 would need to be met.

2. The project sponsor shall require the idling time for off-road and on-road equipment be limited to no more than two minutes, except as provided in exceptions to the applicable state regulations regarding idling for off-road and on-road equipment. Legible and visible signs shall be posted in multiple languages (English, Spanish, Chinese) in designated queuing areas and at the construction site to remind operators of the two minute idling limit.
3. The project sponsor shall require that construction operators properly maintain and tune equipment in accordance with manufacturer specifications.
4. The Plan shall include estimates of the construction timeline by phase with a description of each piece of off-road equipment required for every construction phase. Off-road equipment descriptions and information may include, but is not limited to: equipment type, equipment manufacturer, equipment identification number, engine model year, engine certification (Tier rating), horsepower, engine serial number, and expected fuel usage and hours of operation. For VDECS installed: technology type, serial number, make, model, manufacturer, ARB verification number level, and installation date and hour meter reading on installation date. For off-road equipment using alternative fuels, reporting shall indicate the type of alternative fuel being used.
5. The Plan shall be kept on site and available for review by any persons requesting it and a legible sign shall be posted at the perimeter of the construction site indicating to the public the basic requirements of the Plan and a way to request a copy of the Plan. The project sponsor shall provide copies of Plan to members of the public as requested.

B. Reporting. Monthly reports shall be submitted to the ERO indicating the construction phase and off-road equipment information used during each phase including the information required in A(4). In addition, for off-road equipment using alternative fuels, reporting shall include the actual amount of alternative fuel used.

Within six months of the completion of construction activities, the project sponsor shall submit to the ERO a final report summarizing construction activities. The final report shall indicate the start and end dates and duration of each construction phase. For each phase, the report shall include detailed information required in A(4). In addition, for off-road equipment using alternative fuels, reporting shall include the actual amount of alternative fuel used.

C. Certification Statement and On-site Requirements. Prior to the commencement of construction activities, the project sponsor must certify (1) compliance with the Plan, and (2) all applicable requirements of the Plan have been incorporated into contract specifications.

N/A = Means the risk determination is not appropriate to that receptor.
Values may not add due to rounding.

The MEISR for each off-site receptor type for reduced emissions scenario is the same as for the unreduced emission scenario and is shown on Figure 5, Project Risk MEISR, p. 36. Supporting assumptions and calculations are included in Appendix F and Appendix G, respectively. For on-site residential receptors, the maximum risk would be experienced under Development Scenario B when a receptor is located in Phase 2 during the construction of Phase 3, in Phase 2 during the construction of

Phase 1 and in Phase 1 during the construction of Phase 2. The MEISR shifts for the reduced scenario because there analysis assumes a staged implementation of reduction measures, the level of construction activities and the number of location combinations. Similar to the unreduced scenario, the greatest cancer risk exposure at the daycare site would be experienced during Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3. The MEISR for the daycare does not shift because of the limited locations where the daycare could be located with respect to construction activities.

The MEISR for each off-site receptor type is shown on Figure 5, Project Risk MEISR, p. 36. Because people will relocate to various locations throughout the project site, an MEISR cannot be identified for on-site receptors. However, in Table 11, Reduced Project-Related Risk, p. 39, shows that project related cancer risk for on-site residential uses would range from an excess cancer risk of about 12 to 19. The majority of the anticipated cancer risk is a result of construction emissions. Risks from operational sources (project generated vehicle trips and emergency back-up generator) would be negligible in comparison.

3.5.3 Project-Related $PM_{2.5}$ Concentrations

Table 12, Project-Related $PM_{2.5}$ Concentrations, p. 41, reports the maximum $PM_{2.5}$ concentration as it relates to on-site residential, on-site daycare/preschool uses, off-site residential and off-site school receptors within 1,000 feet of the project boundaries. Total Project $PM_{2.5}$ concentration is conservatively the sum of the maximum annual construction, roadway and stationary source risk as indicated in the table.

Similar to the risk determination, the MEISR for the off-site receptors is a unique location for the residential and school classifications as identified by receptor number and UTM in Table 12, Project-Related $PM_{2.5}$ Concentrations, p. 41. For on-site residential receptors and the daycare receptor, the maximum $PM_{2.5}$ concentrations would be experienced under Development Scenario A.

Implementation of reduction measures RM-2 and RM-3 would also reduce $PM_{2.5}$ concentrations. Table 13, Reduced Project-Related $PM_{2.5}$ Concentrations, p. 42, shows the $PM_{2.5}$ concentrations associated with the Project with the implementation of these reduction measures. The MEISR for the off-site receptors is a unique location for the residential and school classifications. For the residential receptor the implementation of reduction measures causes the MEISR to shift to a different location. For on-site residential receptors, the maximum $PM_{2.5}$ concentrations would be experienced under Development Scenario B when a receptor is located in Phase 2 during the construction of Phase 3, in Phase 2 during the construction of Phase 1 and in Phase 1 during the construction of Phase 2. The MEISR shifts for the reduced scenario because the analysis assumes a staged implementation of reduction measures, the level of construction activities and the number of location combinations. Similar to the unreduced scenario, $PM_{2.5}$ exposure at the daycare site would be highest under Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3. The MEISR for the daycare does not shift because of the limited locations where the daycare could be located with respect to construction activities.

3.6 RESULTS OF CUMULATIVE ANALYSIS

The cumulative air quality analysis looks at the Project's impacts in addition to existing (2014) stationary and mobile sources within the community. The existing stationary and mobile sources within the community were determined from the Citywide modeling.

3.6.1 Cumulative Health Risk

Table 14, Cumulative Risk, p. 43, reports the range of cumulative cancer risk as it relates to on-site residential, on-site daycare/preschool uses, off-site residential and off-site school receptors within 1,000 feet of the project boundaries. Total cumulative risk is the sum of the total Project risk plus the 2014 total risk from the Citywide database as described in Section 1.3, Project Phasing, p. 7. Table 14 represents the maximum or range of anticipated risk for each receptor type.

Table 13 Reduced Project-Related $PM_{2.5}$ Concentrations

Values may not add due to rounding.

The MEISR for each off-site receptor type is identified in Table 14, Cumulative Risk, p. 43, by number and UTM coordinates and are shown on Figure 6, Cumulative Risk MEISR, p. 44. For residential receptors the MEISR would be exposed to the maximum risk under Development Scenario A when a receptor is located in Phase 2 during the construction of Phase 1, in Phase 1 during the construction of Phase 2 and in Phase 2 during the construction of Phase 3. For the daycare site, exposure to the maximum risk would also be experienced during Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3.

Because people will relocate to various locations throughout the project site, an MEISR cannot be identified for on-site receptors. However, as detailed in Section 3.5.1, Project-Related Health Risk, p. 33, this analysis presents a reasonably conservative range of potential risk from the Project.

Values may not add due to rounding.
N/A = Means the risk determination is not appropriate to that receptor.

Implementation of reduction measures RM-2 and RM-3 would also reduce cumulative risk concentrations. Table 15, Reduced Cumulative Risk, p. 45, shows the risk associated with the Project with the implementation of these reduction measures. The MEISR for each off-site receptor type is identified in Table 15 by number and UTM coordinates and are shown on Figure 6, Cumulative Risk MEISR. As noted in the table and shown in Figure 6, the MEISR for the reduced scenario is different for the residential site then for the unreduced scenario. The MEISR shifts for the reduced scenario because the analysis assumes a staged implementation of reduction measures, the level of construction activities and the number of location combinations as well as includes the ambient background risk.

Values may not add due to rounding.
N/A = Means the risk determination is not appropriate to that receptor.

For residential receptors the MEISR would be exposed to the maximum risk under Development Scenario B when a receptor is located in Phase 2 during the construction of Phase 3, in Phase 2 during the construction of Phase 1 and in Phase 1 during the construction of Phase 2. For the daycare site, exposure to the maximum risk would be experienced during Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3.

3.6.2 Cumulative $PM_{2.5}$ Concentrations

Table 16, Cumulative $PM_{2.5}$ Concentrations, p. 46, reports the range of cumulative $PM_{2.5}$ concentrations as it relates to on-site residential, daycare/preschool uses, off-site residential and off-site school receptors within 1,000 feet of the project boundaries. Total cumulative $PM_{2.5}$ concentration is the sum of the total Project concentration plus the 2014 total concentration from the Citywide database. Table 16 represents the maximum for each receptor type.

Table 16 Cumulative $PM_{2.5}$ Concentrations

SOURCE: Atkins (2013).

The MEISR for the off-site receptors is a unique location for the residential and school classifications as identified by receptor number and UTM in Table 16, Cumulative $PM_{2.5}$ Concentrations. For on-site residential receptors, the maximum $PM_{2.5}$ concentrations would be experienced under Development Scenario B when a receptor is located in Phase 2 during the construction of Phase 3, in Phase 2 during the construction of Phase 1 and in Phase 1 during the construction of Phase 2. The MEISR for the daycare site would occur under Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3.

Implementation of reduction measures RM-2 and RM-3 would also reduce Cumulative $PM_{2.5}$ concentrations. Table 17, Reduced Cumulative $PM_{2.5}$ Concentrations, p. 47, shows the cumulative particulate concentrations associated with the Project after the implementation of these reduction measures.

The MEISR for the off-site receptors is a unique location for the residential and school classifications as identified in Table 17, Reduced Cumulative $PM_{2.5}$ Concentrations. For the residential receptor the implementation of reduction measures causes the MEISR to shift to a different location. For on-site residential receptors, the maximum $PM_{2.5}$ concentrations would be experienced under Development Scenario B when a receptor is located in Phase 2 during the construction of Phase 3, in Phase 2 during the construction of Phase 1 and in Phase 1 during the construction of Phase 2. Similar to the unreduced scenario, $PM_{2.5}$ exposure to the daycare site would be experienced during Development Scenario A when the daycare remains in Phase 3 during the development of Phases 1 and 2 then is moved to Phase 2 during the development of Phase 3.

Values may not add due to rounding.

Cumulative annual average $PM_{2.5}$ concentrations would decrease to near ambient levels upon completion of construction activities. Table 18, Reduced Cumulative $PM_{2.5}$ Concentrations At Buildout, p. 48, presents cumulative $PM_{2.5}$ concentration at project buildout for both on-site and off-site sensitive receptors. As discussed in Section 3.4, $PM_{2.5}$ Characterization Methods, p. 32, concentrations for on-site receptors are reported as the maximum concentration determined for all on-site locations. For off-site receptors the reported concentration is associated with the receptor that is exposed to the maximum project-related operational concentration. Therefore, the locations for off-site receptors are not the same as reported in Table 17, Reduced Cumulative $PM_{2.5}$ Concentrations.

CHAPTER 4 Uncertainties

The health risk assessment as presented represents a conservative estimate of health risks from the construction and implementation of the Project. The City of San Francisco, BAAQMD, and Office of Environmental Health Hazard Assessment (OEHHA) guidance for risk assessments provide the methodology for organizing, analyzing, and presenting information on the nature and magnitude of risk to public health from exposure to pollutants. Although these are the most current methodologies available, uncertainties and limitations are still inherent in any health risk assessment. To minimize the consequences of these uncertainties, regulatory guidance relies on the use of conservative estimates. Due to the incorporation of multiple conservative assumptions the overall risk results tend to overestimate the potential risk rather than underestimate it. The following uncertainties underlie this health risk assessment as presented:

1. The methodology used in the calculation of health risks to on-site and off-site receptors is based on the OEHHA methodology. The methodology has exposure durations for residential receptors of 70 years and for student/daycare receptors of nine years. Meaning that residents would be at that location 24 hours per day, 365 days per year for 70 years and for students the assumption is 24 hours per day, 365 days for nine years. This provides a conservatively high estimation of possible risk. Additionally, students at the daycare center would not attend the daycare for nine years as most children begin school at five years of age. However, the methodology does not recommend the use of exposure durations under nine years. Therefore, the exposure of these receptors to risk is overestimated.
2. The risk assessment assumes that some reduction measures would not be implemented until the beginning of the third year of construction. Being that the project is a long-term, multi-year project, there is the potential that the reduction measures would be implemented at the beginning of construction as typically the same equipment would be used throughout the project. Early implementation of the reduction measures would reduce the risk from what is presented.
3. The emissions estimates used to form the basis of the risk for construction assumed that the worst-case scenario would be implemented. In addition, the assumptions that went into determining these emissions are conservative and assume that all equipment in a given Development Phase is operating at the same time throughout the entire construction day. This results in a higher conservative emissions estimate.
4. The risk from roadway sources assumes that the full build-out traffic levels would occur throughout development. While this level of traffic would occur for the majority of the exposure duration used for residential developments, the level of project traffic during construction would only be a fraction of the total level. This is because there would be a slow increase in traffic as the developed phases are occupied and full level of on-site residents would not occur until after the last phase is completed. This is compounded for the school/daycare scenarios as, the exposure duration is only nine years while construction would occur over 10 years. So, there is the potential that some students would never be exposed to the full 10 years of construction plus all traffic emissions.
5. Risk from the operation of the generator assumes that the generator is in operation at the same time as construction and operates at the full permitted level. There is the potential for the generator to operate at the same time as construction is occurring at different locations on site; however, it would not begin operation until at least the end of construction of the second

Development Phase. Therefore, risk is slightly overestimated with respect to generator operations.

6. Risk to on-site receptors included a number of assumptions as to the potential for movement within the Project site while construction activities are taking place. Because the exact nature of the on-site relocations are unknown, the analysis provides for a conservative estimate of emission based on the location exposed to the greatest emissions. A detailed discussion of these uncertainties is provided in Section 3.5.1, Project-Related Health Risk, p. 33.
7. On-site daycare risk was determined as if students were attending from off-site locations. As students would also be living within the community, total risk exposure to these children would be a combination of the risk from their home as well as from this facility. However, it would be lower than the risk identified for the residential receptors.
8. Cumulative risk incorporates emissions from the known environment along with the Project specific risk. The cumulative emissions assume that there is no change in regional off-site emissions over the 70 years. For example, that diesel trucks do not reduce emissions levels, all stationary sources remain operational without implementing more stringent emission reduction requirements, and that no additional stationary sources or increase in roadway volumes occurs. Therefore, this analysis has the potential to over, or underestimate the ambient contribution to risk.

APPENDIX A

Scope Of Work

The methodology used in the analysis of the health risk and the criteria air pollutants were modified from what was documented in the Air Quality Technical Report Scope of Work for the Potrero HOPE SF Master Plan Project EIR – FINAL memorandum. Modifications were coordinated through discussions with EP and another consulting firm in order to standardize the methodology between two similar projects. Therefore, where methodology in the report differs from methodology outlined in the attached memorandum, the methodology in the report supersedes the methodology presented in the following memorandum.

	Preschool/Daycare				3.5	11.368	39.78836	

*Becaue there is no "Senior housing" land use, the "Appartment mid rise" land use was used in the modeling. Because there is no "community center" land use in CalEEMod, the model used the "Library" landuse to approximate emissions from a community center. Further, as there is no "pre-school" land use, the modeling used "day care" to approximate emissions from a presechool.

While only 85% occupency for the whole project, Phase 2 and Phase 3 existing are assumed fully occupied to account for moving occupants of Phase 1 to Phases 2 and 3 while Phase 1 is being rebuilt.

*BAAQMD sets limits to the VOC content for architectural coatings. CalEEMod defaults have been adjusted to meet these requirements. The BAAQMD requirements can be found at: http://www.baaqmd.gov/~/media/Files/Rg8-3_advisory_2_15-2011-FINAL.ashx

Construction Reduction Measures

Reduction Requirements:

RM-1: At the beginning of construction activities, all off-road construction equipment greater than 50 hp shall have engines that meet or exceed USEPA or ARB Tier 3 off-road emission standards, or the Project Sponsor must prepare a construction emissions minimization plan designated to reduce NO_X by a minimum of 39 percent.

RM-2: For all construction occurring after 2016, all off-road construction equipment greater than 50 hp shall have engines that meet or exceed USEPA or ARB Tier 4 interim off-road emission standards, or the Project Sponsor must prepare a construction emissions minimization plan designated to reduce NO_X by a minimum of 21 percent from Tier 3 engines.

Source: Atkins 2013 – CalEEMod Modeling Output.

[a] Net operational build-out is the sum of the operational emissions from all Project Phases and the generator minus the emissions from existing land uses. It represents the anticipated daily or annual emissions after the completion of all construction activities.

b. Under the worst-case development scenario, during years 2015 and 2016, only emissions from construction of the first phase (whether it be Phase 1, or 3) would occur. Note: Under none of the construction scenarios would Phase 2 be developed first.

c. Under the worst-case development scenario, during years 2017 and 2018, only emissions from construction of the first phase would occur if Phase 3 is developed first. If Phase 1 is developed first emissions from these years include the construction activities from subsequent construction phases and the operational activities from the operation of Phase 1.

d. Emissions for Interim Years 2019 through 2025 include emissions from construction activities from subsequent phases and operational activities from operations of previous development phases. For each year, the greatest amount of emissions is reported, regardless of the development scenario. This represents a conservative analysis as depending on the Development Scenario implemented some interim year emissions will be less than reported here.

Memorandum

To: Jessica Range, San Francisco Planning Department, Environmental Planning Division

From: Erin Efner & Heather Dubois, Atkins

Date: October 10, 2012

Subject: Air Quality Technical Report Scope of Work for the Potrero HOPE SF Master Plan Project EIR – FINAL

This memorandum presents the proposed scope of work for the preparation of an Air Quality Technical Report for the Potrero HOPE SF Master Plan Project, as required by the San Francisco Environmental Planning Division (EP), and the 2012 Bay Area Air Quality Management District (BAAQMD) California Environmental Quality Act (CEQA) Guidelines.

This memorandum has been updated to reflect the 3rd set of comments received on October 4, 2011, and EP's revised health risk assessment methodology.

Project Description

The Potrero HOPE SF Master Plan Project would redevelop the Potrero Terrace and Annex (Potrero) housing developments as a part of a program to revitalize distressed public housing developments in San Francisco. The proposed project would replace all 606 existing housing units at the site; incorporate additional affordable housing and market-rate homes into the community; and add amenities such as open space, retail opportunities, and neighborhood services. Including the 606 public housing units, the proposed project would build up to 1,700 homes. The proposed project would include new vehicle connections, new pedestrian connections, a new circulation concept, and new transit stops. In addition, the proposed project would incorporate green construction and sustainable principles.

Development is contemplated to occur in three phases to minimize disruption to existing residents. Phase 1 would likely consist of the vicinity south of 25th Street in the Terrace portion of the project site. Phase 2 would likely consist of the area between 23rd Street and 25th Street, or the remaining portions of the Terrace site. Phase 3 would likely consist of development of the entire Annex site. Where possible, the project would

accommodate on-site relocation of existing residents. Qualified residents would be able to move into the new apartments as they become available.

Grading would be required as a part of project construction. Development of the proposed project would include grading of approximately 39 acres resulting in approximately 248,160 cubic yards (CY) of earthwork over an anticipated three phases of construction. During Phase 1, 18,000 CY of earthwork would be used as fill and 7,400 CY would be exported off site. During Phase 2, 135,680 CY would be excavated and filled on site; however, a total 213,490 CY would be necessary for fill and, as such, 77,810 CY of fill would need to be imported. Therefore, approximately 77,810 CY of fill would be imported to the project site. During Phase 3, 35,730 CY of earthwork would be used as fill and 51,350 CY would be exported off site.

Figure 1 in Attachment A illustrates the project site with a 1,000-foot buffer.

Criteria Pollutants

Criteria pollutants are emitted from project-related construction and operational activities. Emissions are produced from both equipment and dust during construction and renovation activities. Operational emissions generated by project implementation are primarily associated with mobile sources; however natural gas usage, landscaping, and maintenance also contribute to the emission of criteria air pollutants.

1. Project construction-related emissions

Criteria pollutant emissions associated with project-related construction equipment will be estimated using CalEEMod, in accordance with the BAAQMD's 2012 *California Environmental Quality Act Air Quality Guidelines* (Guidelines). Exhaust emissions within the CalEEMod model are evaluated using Off-Road and EMFAC as appropriate for all phases of construction. ROG emissions from construction activities will be determined using the CalEEMod model making adjustments to account for Rule 3 and Reg. 8 and thereby accurately reflect ROG emissions. The inputs for the construction analysis are provided in Attachment B.

These criteria pollutant emissions estimates will be compared to the CEQA thresholds of significance for daily construction emissions and, if appropriate, for annual emissions due to the extended duration of construction. This comparison will serve as the basis for determining if the project would result in a significant adverse impact when compared to the significance criteria and whether Environmental Planning's standard construction mitigation measures would be adequate to reduce impacts to below significance thresholds. Proposed mitigation measures will be discussed with EP prior to their application to the proposed project.

The analysis and results will be included in the Air Quality Technical Report (AQTR) and will include all model default assumptions used, all changes to these default assumptions as well as an explanation as to why default assumptions were changed.

ATKINS

2. Project operational-related emissions

Criteria pollutant emissions associated with the operation of the project will be estimated using CalEEMod, in accordance with the BAAQMD's 2012 Guidelines. Emissions associated with project-related vehicle operations will use trip rates, vehicle trips, and vehicle trip lengths as identified in the project-specific transportation impact analysis.

These criteria pollutant emissions estimates will be compared to the CEQA thresholds of significance for daily and annual operational activities. This comparison will serve as the basis for determining if the project would result in a significant adverse impact and whether features of project design are adequate to reduce emissions or if additional mitigation measures would be required to reduce impacts to below significance thresholds. Should mitigation measures be required, proposed mitigation measures will be discussed with EP prior to their application to the proposed project.

Potential localized carbon monoxide concentrations will be analyzed based on the BAAQMD's screening criteria. The intersection in the 2030 cumulative with project scenario that has the greatest peak hour traffic is Cesar Chavez and Pennsylvania at the NB I-280 off ramp. Total peak hour traffic is 4,320 vehicles[1]. According to the BAAQMD screening criteria, if a project impacted intersection has greater than 44,000 vehicles per hour there is the potential for that project to have significant impacts and should be quantitatively evaluated. As the cumulative plus project scenario's traffic is anticipated to be well below the screening threshold, the analysis will include only a qualitative discussion of localized carbon monoxide impacts.

3. Cumulative Emissions Analysis

The project-level analysis will then be used as a basis for the cumulative impact analysis to determine the project's contribution to significant, cumulative impacts associated with criteria air pollutant and precursor emissions from the proposed project and from other past, present, and reasonably foreseeable future projects in the vicinity.

Health Risk Assessment

Atkins will evaluate the potential for adverse health effects associated with toxic air contaminant (TAC) exposures to residential and other sensitive receptors on and around the project site in the Potrero Hill neighborhood. The Health Risk Assessment will be conducted based on the City's revised methodology. As indicated by the "hot spot" maps, the proposed project is not located within an area that currently has health risks above threshold levels. However, construction for the proposed project is anticipated to extend over a 16 year period and will be located adjacent to sensitive receptors. Due to the size of the project, emissions during construction have the

---

[1] CDM Smith. *Potrero HOPE Transportation Study.* June 5, 2012.

potential to result in a new hot spot. Therefore, EP has determined that a detailed assessment of cancer risk and localized $PM_{2.5}$ concentrations should be conducted for construction activities.

Operational activities will add approximately 12,000 new vehicle trips to the project area as well as introducing two back-up generators that will add additional stationary sources of TACs to the project vicinity. In addition to the risk from construction activities, the health risk assessment will determine excess cancer risk and $PM_{2.5}$ concentrations associated with increased traffic and the new stationary sources.

Off-site receptors evaluated in this HRA will include a representative sample of known residents (child and adult) and school either on the project site and in the surrounding neighborhood and along the expected travel routes of the on-road delivery and haul trucks. The closest sensitive receptor besides the onsite residential uses is the Starr King Elementary School, located immediately west of the project site with outside play areas approximately 15 meters from the project site border.

The health risk assessment for the project will use the AERMOD model and will use the same 20 meter by 20 meter receptor grid for offsite receptors as used for the San Francisco citywide modeling. In addition, because residents of one or more development phases will have occupied the site prior to project build-out, a 10 meter by 10 meter receptor grid will be used to more accurately predict the risks to new, onsite sensitive receptors during the construction modeling. Consistent with the citywide modeling, meteorological data from the Mission Bay Station will be used in the modeling effort.

Subsequent to the modeling efforts, the health risk and $PM_{2.5}$ concentrations from construction and operational activities will be added as additional "project" category for each receptor point with the City's GIS grid system that has the potential to be impacted by the implementation of the project. A 1 kilometer radius surrounding the project site will be used as the area of potential influence for construction and operational activities. Inclusion of the project specific data in the City's GIS database will allow total cancer risk and total $PM_{2.5}$ concentrations to be determined for each receptor by summing all of the sources (i.e. existing, plus ambient ($PM_{2.5}$), plus project construction, plus project operation). The maximum exposed individual (MEI) will then be determined and significance conclusions can be made. For construction, because the on-site receptor grid will be 10 meters by 10 meters, Atkins will prepare a separate table listing the receptor points and construction PM2.5 concentrations and cancer risk at each point.

The determination of significance will be based on whether the project would result in new hot spots at any one receptor point. A hot spot is defined as any receptor point that exceeds the following standards:

- A cancer risk of 100 in a million when project cancer risk is added to the cancer risk from all other sources in the vicinity; and

ATKINS

- A cumulative $PM_{2.5}$ concentration of 10 $\mu g/m^3$ (project concentrations, in addition to $PM_{2.5}$ concentrations from nearby sources and including the ambient concentration of 8.06 $\mu g/m^3$).

Should impacts exceed the above acceptable levels of risk and $PM_{2.5}$ concentrations, mitigation measures will be proposed to reduce the potential health risk. All mitigation measures will be discussed with EP prior to implementation and a mitigated risk level will be included as part of the health risk assessment.

1. Project construction-related emissions

Emissions from the equipment exhaust associated with the project construction activities will be estimated based on construction site locations, construction scheduling and timelines, and equipment type/use intensity data provided by the project sponsor. Construction activities considered in this HRA include project-related demolition, grading, excavation, infrastructure installation and foundation and structure construction. Construction emissions sources will include off-road construction equipment (e.g., cranes, loaders, excavators, dozers, graders, etc.) and construction-related motor vehicle traffic, the latter including:

- Equipment and material delivery trucks,
- Spoils and debris hauling trucks, and
- Construction employee commute vehicles.

Haul truck and vehicle commute emissions will be limited to emissions from these trips that would occur on-site and within 1,000 feet from the site or to the freeway entrance along local roadways. Because the majority of impacts are expected to be from the continued exposure to on-site equipment usage with respect to nearby sensitive receptors, as haul trucks and vehicle commutes are removed from the immediate vicinity of the construction, their emissions will no longer affect the receptors within the immediate vicinity of the construction activities. Exhaust emissions will be determined using the emission factors in EMFAC (2011) and OFFRoad (2011 or 2007 as applicable) as determined through use of the CalEEMod emissions model as appropriate. Attachment B contains the data that has been collected from the project applicant that will be input into the model.

Based on current project information, it is anticipated that while construction occurs at some parcels, existing residents will continue to reside at unaffected parcels and/or existing/future residents will be relocated/moved-in to newly constructed units. Thus, on-site receptors evaluated in this HRA will include the existing residents who continue to reside on-site during construction and future residents coming in to occupy the units newly built on-site during latter construction phases.

Construction is anticipated to occur in three phases, with Phase 1 being the southernmost portion of the site, Phase 2 being the central portion, and Phase 3 being the northern portion. For on-site areas undergoing construction, no receptors would be

present and therefore these areas will not show risks and hazards. However, other on-site areas where residents would be located or relocated would show risks and hazards for that particular phase to reflect the intention that residents would be relocated on-site during construction. In order to more accurately assess risk, each phase will be modeled separately and risk for discrete receptors will be estimated based on a conservative worst-case construction scenario for each phase.

It is anticipated that construction vehicles will approach the site from I-280 via Cesar Chavez Street or Pennsylvania Avenue, or the U.S.101/I-80 freeways from Cesar Chavez Street and, therefore, will traverse through the industrial portion of the zone of influence rather than the residential sector, thus limiting impacts to sensitive receptors. The construction route will be confirmed with the Client prior to modeling so the most accurate impacts from haul trucks can be assessed.

As indicated, construction modeling will be conducted using AERMOD with the citywide receptor grid for offsite sources, and a 10 meter receptor grid for onsite sources. Construction sources will be modeled as volume sources and haul trips will be modeled as line sources.

2. Emissions associated with the operation of on-site permitted stationary TAC sources and increased area traffic volumes.

It is assumed that two emergency generators would be required. This health risk analysis will evaluate the potential impacts of two emergency generators along 24th Street in the proposed buildings between Arkansas and Missouri Streets. The emergency generators would be within 15 meters of residential units.

Emissions from the on-site emergency generators will be estimated based on project specific operating parameters, i.e. the operation of the generator for 40 to 50 hrs per year, and the specifications of an appropriately sized Tier 3 or Tier 4 compliant generator as specified by the project sponsor. Written confirmation regarding the generator's EPA compliance and the project applicant's commitment to use a specific EPA Tier generator will be provided to EP along with stack parameters before modeling begins along with specific generator locations. Generators will be modeled in AERMOD as point sources.

Implementation of the proposed project will result in an increase in area traffic by approximately 12,000 daily trips[2]. Under existing conditions, Potrero Avenue, Cesar Chavez Street, and Pennsylvania Street have the greatest levels of traffic at 18,510, 15,610, and 13,180 trips, respectfully. At 2030, these levels are anticipated to increase to 25,660 for Potrero Ave, 29,910 for Cesar Chavez Street, and 18,110 for Pennsylvania Street without project implementation. These levels increase to 26,370,

[2] CDM Smith. *Potrero HOPE Transportation Study.* June 5, 2012.

33,220, and 18,640 respectively with project specific traffic. While other roadways will see an increase in traffic as well, these three have the greatest increase and will be used to represent the potential increase in risk to determine if new hotspots are created from traffic increases in the area. These sources will be modeled under existing plus project contribution at full buildout to estimate a worse case project impacts. An additional modeling scenario will be conducted to determine risk from cumulative plus project conditions to show a maximum cumulative risk based on anticipated area growth. Roadways sources will be modeled as line sources. Vehicle emissions will be estimated from EMFAC 2011 which takes into account increasing vehicle regulations.

Technical Report

The Technical Report will follow the format of CEQA Air Quality Technical Report prepared by EP and will include the following components: Project Description, Project Setting, Criteria Air Pollutants, Health Risk Analysis, Conclusion, Approved Scope of Work, and Technical Appendices which will include detailed modeling assumptions, calculations, and output, applicable correspondence, and appropriate reference materials.

NOTES
All Mass Excavation figured using scrapers
No Rock Excavation figured
All Utilities figured at depth 5' or less

Joint Trench figured at 3' depth
Manholes figured at 8'x8'
Laterals figured at 3'x50'
Storm Catch Basin figured at 5'x5'x5'
Water Pipe, Valves, & Blow Offs by City
Remedial Earthwork is assumed limited to off haul quantities only, covering additional travel to appropriate dispo

4.0 Mobile Detail

4.1 Mitigation Measures Mobile

Potrero Phase 3 Construction

San Francisco County, Annual

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric
Apartments Low Rise	207	Dwelling Unit
Condo/Townhouse	458	Dwelling Unit
Strip Mall	5	1000sqft

1.2 Other Project Characteristics

Urbanization	Urban	**Wind Speed (m/s)**	4.6	**Utility Company**	Pacific Gas & Electric Company
Climate Zone	5	**Precipitation Freq (Days)**	64		

1.3 User Entered Comments

Project Characteristics - Criteria pollutant emissions for Phase 3 construction

Land Use - Based on project specific data

Construction Phase - Based on project specific data

Off-road Equipment -

Off-road Equipment - based on project specific data

Off-road Equipment - based on project specific data

Off-road Equipment - based on project specific data

Trips and VMT - based on project specific data and 20 cys per truck

Demolition -

Grading - based on project site size

Architectural Coating - based on BAAQMD g/l VOC requirements

Vehicle Trips - no operation

Woodstoves - no operation

Area Coating - no operation

Landscape Equipment - no operation

Energy Use -

Construction Off-road Equipment Mitigation -

Area Mitigation - need to reduce VOC emissions.

4.0 Mobile Detail

4.1 Mitigation Measures Mobile

APPENDIX D

Project Operational CalEEMod Output

It was originally assumed that fireplaces would be used in the analysis. However, subsequent to the original modeling, it was determined that fireplaces would not be incorporated into the project. As a ban on fireplaces was the only reduction measure incorporated into the operational analysis, the "mitigated" values in the following CalEEMod models actually represent the "unreduced" Project emissions.

Potrero HOPE
Operational Summary Tables

Operational Emissions

	ROG	NO_X	PM_{10}	$PM_{2.5}$
Daily Emissions (lbs/day)				
Existing	32.69	32.46	0.86	0.86
Phase 1	13.89	12.69	0.46	0.46

2021-2025 Interim[2]	10.28	15.63	0.66	0.80

Source: Atkins 2013 – CalEEMod Modeling Output.

[1] Interim year 2017 - 2021 includes the operational emissions of phase 1,and the average daily or annual construction emissions for Phase 2. Further, it reduces emissions by the percentage of existing homes that were demolished as part of Phase 1 construction.

[2] Interim year 2021 - 2025 includes the operational emissions of phase 1, phase 2, the generators, and the average daily or annual construction emissions for Phase 3. Further, it reduces emissions by the percentage of existing homes that were demolished as part of Phase 1 and Phase 2 construction.

Net Reduced Operational Emissions

Pennsylvania St	520	4.09E-04	551.2	0.23	7.38E-05

[1] Traffic values from Traffic Study. Existing is 2010

[2] Speed is existing speed limits for the roadways in question in miles per hour.

[3] Miles = Roadway segment segment length based on BAAQMD Recommended Methods for Screening and Modeling Local Risks and Hazards. May 2012.

[4] G/mile are averages taken from EMFAC2011.

[5] Total project miles are determined by roadway length times the number of vehicles.

[7] Grams = grams/mile * miles

Potrero HOPE
HRA Assumptions - Generators

**We do not have project specifics as to exact locations or type of generator. The generators will be located with the Community center and we assumed they would be at the southeast corner of the property as the wind is predominately from the northwest. Assumed generators would have EPA Tier 2 engines and assumed high horsepower generators and operating for the full permitted 50 hours per year as a worst case.*

Generator Model used: Cat: 750 ekW 938 kVA 60 Hz 1800 rpm 480 Volts

	X	Y	Exit Temp	Stack Diameter	Exit Flow Rate	
	UTM		°F	ft	cfm	HP
1	553152.33	4178608.18	948.7	0.667	5611.5	1100
2	553148.39	4178608.18	948.7	0.667	5611.5	1100

Emission (per generator)

	(g/hp-h)	HP	hours/year	g/year	g/sec	lbs/day
NO_X	5.25	1100	50	288750	0.219749	1.74
CO	0.25	1100	50	13750	0.010464	0.08
PM	0.021	1100	50	1155	0.000879	0.01

lbs/gr:	0.0022
g/yr to g/s:	1,314,000

Potrero HOPE
Receptor ID /AIRID Comparison

The Receptor number from the AERMOD database does not match the AIR ID number from the Citywide Database due to the inclusion of the 10 x 10 receptor grid. Therefore a side by side comparison of AERMOD ID to AIRID is shown here based on the UTM coordinates for each receptor. RISK and PM2.5 concentrations are reported based on AIR ID number.

Potrero HOPE

Risk Calculation Factors By Source - Unmitigated

Tier 2 Uncontrolled Emissions

Dose = Dose through inhalation (mg/kg/day)

10^{-6} = Micrograms to milligram conversion and liters to cubic meters conversion.

DBR = Daily Breathing Rate (L/kg bodyweight – day) (302 – 80th percentile for residential; 581 school/daycare)

A = Inhalation absorption factor (1)

EF = Exposure frequency (construction/school 260 days per year, residential 350 days per year)

ED = Exposure duration (years)

AT = Averaging time period over which exposure is averaged (days) (25,550 days)

CRAF/ASF = Age sensitivity factor. Note for Roadways for both DPM and TOG the CRAF/ASF has been incorporated into the emission factor for residential purposes. Schools and daycare/preschool facilities have a CRAF of 3 and 10 repsectively. For onsite child resident over the 10 year construction periond, age sensitivity factor is 4.4. For daycare/preschool - Risk is derived based on 2 years at a CRAF of 10 and 3 years at a CRAF of 3.

4.4 assumes birth to 10 years

Potrero HOPE

Risk Calculation Factors By Source - Reduced Scenario A

Dose = Dose through inhalation (mg/kg/day)

10^{-6} = Micrograms to milligram conversion and liters to cubic meters conversion.

DBR = Daily Breathing Rate (L/kg bodyweight – day) (302 – 80th percentile for residential; 581 school/daycare)

A = Inhalation absorption factor (1)

EF = Exposure frequency (construction/school 260 days per year, residential 350 days per year)

ED = Exposure duration (years)

AT = Averaging time period over which exposure is averaged (days) (25,550 days)

CRAF/ASF = Age sensitivity factor. Note for Roadways for both DPM and TOG the CRAF/ASF has been incorporated into the emission factor for residential purposes. Schools and daycare/preschool facilities have a CRAF of 3 and 10 repsectively. For onsite child resident over the 10 year construction periond, age sensitivity factor is 4.4. For daycare/preschool - Risk is derived based on 2 years at a CRAF of 10 and 3 years at a CRAF of 3.
